#### Abstract

This research paper is based on the estimation of errors in the formulas which are used to obtaining intermediate values of the rate of enzymatic reaction. The rate of enzymatic reaction is affected by concentration of substrate, Temperature, concentration of enzyme and other factors. The rise in Temperature accelerates an Enzyme reaction. At certain Temperature known as the optimum Temperature the activity is maximum. The concentration of substrate is the limiting factor, as the substrate concentration increases, the Enzyme reaction rate increases. Assuming a sufficient concentration of substrate is available, increasing Enzyme concentration will increase the enzymatic reaction rate. These formulas are derived from temperature, substrate concentration and enzyme concentration based mathematical functions. These formulas are used to obtaining intermediate values of the rate of enzymatic reaction. Formulas which are derived using Newton's method for interpolation are worked in conditions which are depending on the point lies. If the point lies in the upper half then used Newton's forward interpolation formula. If the point lies in the lower half then we used Newton's backward interpolation formula. And when the interval is not equally spaced then used Newton's divide difference interpolation formula. When the tabulated values of the function are not equidistant then used Lagrangian polynomial. Mathematical expressions are derived for estimation of errors using intermediate values and formulas. All expressions are worked in $n$ limit which is the optimum limit.

Keywords: Estimation of Errors, Intermediate values, Mathematical Expressions, Rate of enzymatic reaction.

## 1 INTRODUCTION

Temperature, concentration of substrate, concentration of enzyme and other factors are affected the rate of enzymatic reaction [1]. The rise in Temperature accelerates an Enzyme reaction but at the same time causes inactivation of the protein. At certain Temperature known as the optimum Temperature the activity is maximum. The concentration of substrate is the limiting factor, as the substrate concentration increases, the Enzyme reaction rate increases. Assuming a sufficient concentration of substrate is available, increasing Enzyme concentration will increase the enzymatic reaction rate. Temperature, concentration of substrate and concentration of enzyme are increased the rate of enzymatic reaction at a limit which is called optimum limit [2]. On the basis of this concept, there are three mathematical functions [1] [2]:

$$
\begin{aligned}
& V=f(T) \\
& V=f(S) \\
& V=f(E)
\end{aligned}
$$

Where $V$ is the rate of enzymatic reaction, $T$ is the temperature, $S$ is the concentration of substrate and $E$ is the concentration of enzyme. These functions are be in $n$ intervals and $n$ is the optimum limit [1]. Some formulas are derived on the basis of these functions using Newton's method for interpolation and Lagrangian polynomial. These formulas are used to obtaining intermediate values of the rate of enzymatic reaction. Formulas which are derived using Newton's method for interpolation are worked in conditions which are depending on the point lies. If the point lies in the upper half then used Newton's forward interpolation formula. If the point lies in the lower half then we used Newton's backward interpolation

Estimation of Errors: Mathematical Expressions of Temperature, Substrate Concentration and Enzyme Concentration based Formulas for obtaining intermediate values of the Rate of Enzymatic Reaction
formula. And when the interval is not equally spaced then used Newton's divide difference interpolation formula. When the tabulated values of the function are not equidistant then used Lagrangian polynomial [3]-[14].

## 2 FORMULAS FOR OBTAINING INTERMEDIATE VALUES OF V WITH TEMPERATURE

Let $V=f(T)$ be a function defined by $n$ points $\left(T_{0}, V_{0}\right),\left(T_{1}, V_{1}\right) \ldots \ldots \ldots .\left(T_{n}, V_{n}\right)$. Where $V$ is the rate of reaction and $T$ is the Temperature of reaction. And other factors are to be constant [1][2]. When $T_{1}, T_{2}, T_{3} \ldots \ldots \ldots \ldots . . T_{n}$ are equally spaced with interval $h$.

### 2.1 If THE POINT LIES IN THE UPPER HALF

In this condition we used following formula [1]:
$V(T)=V_{0}+\Delta V_{0}(u)+\frac{\Delta^{2} V_{0}}{2!}(u)[(u-1)] \ldots .+\frac{\Delta^{n} V_{0}}{n!}[(u)\{(u-1)\} \ldots \ldots .\{(u-n\}]$
[Where $\Delta$ is forward difference operator and $\frac{T-T_{0}}{h}=u$ ]

### 2.1.1 Estimation of ERROR

Let $V=f(T)$ be a function defined by $(n+1)$ points $\left(T_{0}, V_{0}\right),\left(T_{1}, V_{1}\right) \ldots \ldots \ldots .\left(T_{n}, V_{n}\right)$. When $T_{1}, T_{2}, T_{3} \ldots \ldots \ldots \ldots . . . T_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(T)$ be approximated by a polynomial $P_{n}(T)$ of degree not exceeding a such that
$P_{n}\left(T_{i}\right)=V_{i} \quad[$ Where $i=1,2,3 \ldots \ldots \ldots . n]$
Since the expression $f(T)-P_{n}(T)$ vanishes for $T_{1,} T_{2}, T_{3} \ldots \ldots \ldots \ldots T_{n}$,
We put $f(T)-P_{n}(T)=K \phi(T)$
Where $\phi(T)=\left(T-T_{0}\right)\left(T-T_{1}\right) \ldots \ldots \ldots \ldots . .\left(T-T_{n}\right)$
And $K$ is to be determined in such a way that equation (2) holds for any intermediate values of $T$, say $T-T^{\prime}$ $\left[\right.$ where $T_{0} \leq T^{\prime} \leq T_{n}$ ].

Therefore from (2)

$$
\begin{equation*}
K=\frac{f\left(T^{\prime}\right)-P\left(T^{\prime}\right)}{\varphi\left(T^{\prime}\right)} \tag{4}
\end{equation*}
$$

Now we construct a function $f(T)$ such that

$$
f\left(T_{0}\right)=f\left(T_{1}\right)-P_{n}(T)-K \varphi(T)
$$

Where $K$ is given by equation (4).
It is clear that

$$
\begin{equation*}
f\left(T_{0}\right)=f\left(T_{1}\right)=f\left(T_{2}\right)=f\left(T_{3}\right)=\ldots \ldots \ldots \ldots f\left(T_{n}\right)=f\left(T^{\prime}\right)=0 \tag{5}
\end{equation*}
$$

Let $f(T)$ vanishes $(n+2)$ times in the interval $T_{0} \leq T \leq T_{n}$; consequently, by the repeated application of Rolle's Theorem [15] [16], $f^{\prime}(T)$ must vanish $(n+1)$ times, $f^{\prime \prime}(T)$ must vanish $n$ times etc in the interval $T_{0} \leq T \leq T_{n}$.

Particularly, $f^{(n+1)}(T)$ must vanish once in the interval $T_{0} \leq T \leq T_{n}$. Let this point be $T=Z, T_{0}<Z<T_{n}$.

Now differentiating equation (5) (n+1) times with respect to $T$ and putting $T=Z$, we got:

$$
\begin{array}{r}
f^{(n+1)}(Z)-K(n+1)!=0 \\
\text { Or } \quad K=\frac{f^{(n+1)}(Z)}{(n+1)!}
\end{array}
$$

Putting this value of $K$ in equation (4), we got:

Or

$$
\begin{aligned}
& \frac{f^{(n+1)}(Z)}{(n+1)!}=\frac{f\left(T^{\prime}\right)-P_{n}\left(T^{\prime}\right)}{\varphi\left(T^{\prime}\right)} \\
& f\left(T^{\prime}\right)-P_{n}\left(T^{\prime}\right)=\frac{f^{(n+1)}(Z)}{(n+1)!} \varphi\left(T^{\prime}\right), \quad T_{0}<Z<T_{n}
\end{aligned}
$$

Since $T^{\prime}$ is arbitrary therefore on dropping the prime on $T^{\prime}$ we got:

$$
\begin{equation*}
f(T)-P_{n}(T)=\frac{f^{(n+1)}(Z)}{(n+1)!} \varphi(T), \quad T_{0}<Z<T_{n} \tag{7}
\end{equation*}
$$

Now we use Taylor's theorem [17] [18]:
$f(T+h)=f(Z)+h f^{\prime}(Z)+\frac{h^{2}}{2!} f^{\prime \prime}(Z)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(Z)+\ldots .$.
Neglecting the terms containing second and higher powers of $h$ in equation (8), we got:

$$
f(Z+h)=f(Z)+h f^{\prime}(Z)
$$

Or

$$
\begin{equation*}
f^{\prime}(Z)=\frac{f(Z+h)-f(Z)}{h} \tag{9}
\end{equation*}
$$

Or

$$
\begin{aligned}
& f^{\prime}(Z)=\frac{1}{h} \Delta f(Z) \quad[\therefore \Delta f(T+h) f(T)] \\
& D f(Z)=\frac{1}{h} \Delta f(Z) \quad \quad\left[\therefore D=\frac{d}{d Z}\right] \\
& D=\frac{1}{h} \Delta \quad \quad \text { Because } f(Z) \text { is arbitrary] } \\
& \therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{aligned}
$$

From equation (9), we got:

$$
f^{(n+1)}(Z)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Z)
$$

Putting the values of $f^{(n+1)}(Z)$ in equation (7), we got

$$
f(T)-P_{n}(T)=\left[\frac{\varphi(T)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Z)\right]
$$

$f(T)-P_{n}(T)=\left[\frac{\left(T-T_{0}\right)\left(T-T_{1}\right)\left(T-T_{2}\right) \ldots \ldots \ldots \ldots \ldots . .\left(T-T_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Z)\right]$

If $\frac{T-T_{0}}{h}=u$
Then

$$
\begin{aligned}
& T-T_{0}=h u \\
& T-T_{1}=T-\left(T_{0}+h\right)=\left(T-T_{0}\right)-h=(h u-h)=h(u-1)
\end{aligned}
$$

Similarly $T-T_{2}=h(u-2)$
:
:

Similarly $T-T_{n}=h(u-n)$
Putting these values in equation (10), we got:

$$
\begin{aligned}
& f(T)-P_{n}(T)=\left[\frac{(h u)\{h(u-1)\}\{h(u-2)\}\{h(u-3)\} \ldots \ldots \ldots \ldots \ldots .\{(u-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Z)\right] \\
& f(T)-P_{n}(T)=\left[\frac{u(u-1)(u-2)(u-3) \ldots \ldots \ldots .(u-n)}{(n+1)!}\right]\left[\Delta^{(n+1)} f(Z)\right]
\end{aligned}
$$

This is mathematical expression for estimation of error, if the point lies in the upper half.

### 2.2 If the point lies in the lower half

In this condition we used following formula [1]:
$\mathrm{V}(\mathrm{T})=\mathrm{V}_{\mathrm{n}}+\nabla \mathrm{V}_{\mathrm{n}}(\mathrm{z})+\frac{\nabla^{2} \mathrm{~V}_{\mathrm{n}}}{2!}[\{\mathrm{z}(\mathrm{z}+1)\}]+\ldots . .+\frac{\nabla^{n} \mathrm{~V}_{\mathrm{n}}}{\mathrm{n}!}[(\mathrm{z})\{(\mathrm{z}+1)\} .\{\mathrm{z}+(\mathrm{n}-1)\}]$
[Where $\nabla$ is backward difference operator and $\frac{T-T_{n}}{h}=z$ ]

### 2.2.1 ESTIMATION OF ERROR

Let $V=f(T)$ be a function defined by $(n+1)$ points $\left(T_{0}, V_{0}\right),\left(T_{1}, V_{1}\right)$ $\qquad$ $\ldots\left(T_{n}, V_{n}\right)$. When $T_{1}, T_{2}, T_{3} \ldots$ $\qquad$ $T_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(T)$ be approximated by a polynomial $P_{n}(T)$ of degree not exceeding a such that
$P_{n}\left(T_{i}\right)=V_{i} \quad[$ Where $i=1,2,3 \ldots \ldots \ldots . n]$
Since the expression $f(T)-P_{n}(T)$ vanishes for $T_{1}, T_{2}, T_{3} \ldots \ldots \ldots \ldots . .$.
We put $f(T)-P_{n}(T)=K \phi(T)$
Where $\phi(T)=\left(T-T_{n}\right)\left(T-T_{n-1}\right)$ $\qquad$ .$\left(T-T_{0}\right)$

And $K$ is to be determined in such a way that equation (12) holds for any intermediate values of $T$, say $T-T^{\prime}$ [where $T_{0} \leq T^{\prime} \leq T_{n}$ ].

Therefore from equation (12),

$$
\begin{equation*}
K=\frac{f\left(T^{\prime}\right)-P\left(T^{\prime}\right)}{\varphi_{1}\left(T^{\prime}\right)} \tag{14}
\end{equation*}
$$

Now we construct a function $f(T)$ such that

$$
f\left(T_{0}\right)=f\left(T_{1}\right)-P_{n}(T)-K \varphi_{1}(T)
$$

Where $K$ is given by equation (14).
It is clear that
$f\left(T_{0}\right)=f\left(T_{1}\right)=f\left(T_{2}\right)=f\left(T_{3}\right)=\ldots \ldots \ldots \ldots . . . f\left(T_{n}\right)=f\left(T^{\prime}\right)=0$
Let $f(T)$ vanishes ( $\mathrm{n}+2$ ) times in the interval $T_{0} \leq T \leq T_{n}$; consequently, by the repeated application of Rolle's Theorem [15] [16], $f^{\prime}(T)$ must vanish $(n+1)$ times, $f^{\prime \prime}(T)$ must vanish $n$ times etc in the interval $T_{0} \leq T \leq T_{n}$.

Particularly, $f^{(n+1)}(T)$ must vanish once in the interval $T_{0} \leq T \leq T_{n}$. Let this point be $T=Y, T_{0}<Z<T_{n}$.
Now differentiating equation (15) $(n+1)$ times with respect to $T$ and putting $T=Y$, we got:

Or

$$
\begin{gather*}
f^{(n+1)}(Y)-K(n+1)!=0 \\
K=\frac{f^{(n+1)}(Y)}{(n+1)!} \tag{16}
\end{gather*}
$$

Putting this value of $K$ in equation (14), we got:

Or

$$
\frac{f^{(n+1)}(Y)}{(n+1)!}=\frac{f\left(T^{\prime}\right)-P_{n}\left(T^{\prime}\right)}{\varphi_{1}\left(T^{\prime}\right)}
$$

$$
f\left(T^{\prime}\right)-P_{n}\left(T^{\prime}\right)=\frac{f^{(n+1)}(Y)}{(n+1)!} \varphi_{1}\left(T^{\prime}\right), \quad T_{0}<Y<T_{n}
$$

Since $T^{\prime}$ is arbitrary therefore on dropping the prime on $T^{\prime}$ we got:

$$
\begin{equation*}
f(T)-P_{n}(T)=\frac{f^{(n+1)}(Y)}{(n+1)!} \varphi_{1}(T), \quad T_{0}<Y<T_{n} \tag{17}
\end{equation*}
$$

Now we use Taylor's theorem [17] [18]:
$f(T+h)=f(Y)+h f^{\prime}(Y)+\frac{h^{2}}{2!} f^{\prime \prime}(Y)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(Y)+\ldots .$.
Neglecting the terms containing second and higher powers of $h$ in equation (18), we got:

Or

$$
f(Y+h)=f(Y)+h f^{\prime}(Y)
$$

$$
\begin{equation*}
f^{\prime}(Z)=\frac{f(Y+h)-f(Y)}{h} \tag{19}
\end{equation*}
$$

Or

$$
f^{\prime}(Z)=\frac{1}{h} \Delta f(Y) \quad[\therefore \Delta f(T+h) f(T)]
$$

$$
D f(Y)=\frac{1}{h} \Delta f(Y)
$$

$$
\left[\therefore D=\frac{d}{d Y}\right]
$$

$$
\begin{aligned}
& \left.D=\frac{1}{h} \Delta \quad \quad \text { [Because } f(Y) \text { is arbitrary }\right] \\
& \therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{aligned}
$$

From equation (19), we got:

$$
f^{(n+1)}(Y)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Y)
$$

Putting the values of $f^{(n+1)}(Y)$ in equation (17), we got:

$$
\begin{array}{r}
f(T)-P_{n}(T)=\left[\frac{\varphi_{1}(T)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Y)\right] \\
f(T)-P_{n}(T)=\left[\frac{\left(T-T_{0}\right)\left(T-T_{1}\right)\left(T-T_{2}\right) \ldots \ldots \ldots \ldots \ldots .\left(T-T_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Y)\right] \tag{20}
\end{array}
$$

If $\frac{T-T_{n}}{h}=z$
Then

$$
\begin{aligned}
& T-T_{n}=h z \\
& T-T_{n-1}=T-\left(T_{n}-h\right)=\left(T-T_{n}\right)+h=(h z+h)=h(z+1)
\end{aligned}
$$

Similarly $T-T_{n-2}=h(z+2)$

Similarly $T-T_{0}=h(z+n)$
Putting these values in equation (20), we got:

$$
f(T)-P_{n}(T)=\left[\frac{(h z)\{h(z-1)\}\{h(z-2)\}\{h(z-3)\} \ldots \ldots \ldots \ldots \ldots\{(z-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Y)\right]
$$

This is mathematical expression for estimation of error, if the point lies in the lower half.

### 2.3 If Intervals are not be equally spaced

In this condition we used following formula [1]:

$$
\mathrm{V}(\mathrm{~T})=\mathrm{V}_{1}+\Delta_{\mathrm{d}} \mathrm{~V}_{1}\left(\mathrm{~T}-T_{1}\right)+\Delta_{\mathrm{d}}^{2} \mathrm{~V}_{1}\left(\mathrm{~T}-T_{1}\right)\left(\mathrm{T}-T_{2}\right)+\ldots . .+\Delta_{\mathrm{d}}^{\mathrm{n}} \mathrm{~V}_{1}\left[\left(\mathrm{~T}-\mathrm{T}_{1}\right)\left(\mathrm{T}-T_{2}\right) \ldots\left(\mathrm{T}-\mathrm{T}_{\mathrm{n}}\right)\right]
$$

[Where $\Delta_{d}$ is divide difference operator]

### 2.3.1 Estimation of ERROR

Let $f(T)$ be a real-valued function define $n$ interval and $(n+1)$ times differentiable on $(a, b)$. If $P n(T)$ is the polynomial. Which interpolates $f(T)$ at the $(n+1)$ distinct points $T_{0}, T_{1} \ldots . . T_{n} \in(a, b)$, then for all $\bar{T} \in[a, b]$, there exists $\xi=\xi(\bar{T}) \in(a, b)$

$$
\begin{align*}
e_{n}(\bar{T}) & =f(\bar{T})-P_{n}(\bar{T}) \\
& =\frac{f^{(n+1)}(\xi)}{(n+1)} \prod_{j=0}^{n}\left(\bar{T}-T_{j}\right) \tag{21}
\end{align*}
$$

This is mathematical expression for estimation of error, if intervals are not be equally spaced.

### 2.4 When the tabulated values of the function are not equidistant

In this condition we used following formula [2]:

$$
\mathrm{V}(\mathrm{~T})=\sum_{i=1}^{n} \mathrm{~V}_{i} \prod_{\substack{j=1 \\ j \neq i}}^{n} \frac{\left(\mathrm{~T}-\mathrm{T}_{j}\right)}{\left(\mathrm{T}_{i}-\mathrm{T}_{j}\right)}
$$

### 2.4.1 EStIMATION OF ERROR

Since the approximating polynomial $f(T)$ given by Lagrangian formula has the same values $f\left(T_{0}\right) f\left(T_{1}\right) f\left(T_{2}\right)$ $f\left(T_{3}\right) f\left(T_{4}\right) \ldots \ldots . . . . . . f\left(T_{n}\right)$ as does $V=f(T)$ for the arguments $T_{0}, T_{1}, T_{2}, T_{3}, T_{4} \ldots \ldots . . . . . . . . . . . ., T_{n}$ the error term must have zeros at these $(n+1)$ points.

Therefore $\left(T-T_{0}\right)\left(T-T_{1}\right)\left(T-T_{2}\right)\left(T-T_{3}\right)$........................... $\left(T-T_{n}\right)$ must be factors of the error and we can write:

$$
\begin{equation*}
F(T)=f(T)+\frac{\left(T-T_{0}\right)\left(T-T_{1}\right)\left(T-T_{2}\right)\left(T-T_{3}\right) \ldots \ldots \ldots \ldots \ldots . .\left(T-T_{n}\right)}{(n+1)!} K(T) \tag{22}
\end{equation*}
$$

Let $T$ to be fixed in value and consider the function

$$
\begin{equation*}
W(x)=F(x)-f(x) \frac{\left(x-T_{0}\right)\left(x-T_{1}\right)\left(x-T_{2}\right)\left(x-T_{3}\right) \ldots \ldots \ldots \ldots \ldots .\left(x-T_{n}\right)}{(n+1)!} K(T) \tag{23}
\end{equation*}
$$

Then $W(x)$ has zero $x=T_{0}, T_{1}, T_{2}, T_{3} \ldots \ldots \ldots \ldots . . T_{n}$ and $T$.
Since the $(n+1)^{\text {th }}$ derivative of the $n^{\text {th }}$ degree polynomial $f(T)$ is zero.

$$
\begin{equation*}
W^{(n+1)}(x)=F^{(n+1)}(x)-K(T) \tag{24}
\end{equation*}
$$

As a consequence of Rolle's Theorem [15] [16], the $(n+1)^{t h}$ derivative of $W(x)$ has at least one real zero $x=\xi$ in the range $T_{0}<\xi<T_{n}$

Therefore substituting $x=\xi$ in equation (24)

Or

$$
W^{(n+1)}(\xi)=F^{(n+1)}(\xi)-K(T)
$$

$$
\begin{aligned}
K(T) & =F^{(n+1)}(\xi)-W^{(n+1)}(\xi) \\
& =F^{(n+1)}(\xi)
\end{aligned}
$$

Using this expression for $K(T)$ and writing out $f(T)$

Estimation of Errors: Mathematical Expressions of Temperature, Substrate Concentration and Enzyme Concentration based Formulas for obtaining intermediate values of the Rate of Enzymatic Reaction

$$
\begin{aligned}
& f(T)=\frac{\left(T-T_{1}\right)\left(T-T_{2}\right) \ldots \ldots \ldots \ldots . .\left(T-T_{n}\right)}{\left(T_{0}-T_{1}\right)\left(T_{0}-T_{2}\right) \ldots \ldots \ldots \ldots .\left(T_{0}-T_{n}\right)} f\left(T_{0}\right)+\frac{\left(T-T_{0}\right)\left(T-T_{2}\right) \ldots \ldots \ldots \ldots . .\left(T-T_{n}\right)}{\left(T_{1}-T_{0}\right)\left(T_{1}-T_{2}\right) \ldots \ldots \ldots . .\left(T_{1}-T_{n}\right)} f\left(T_{1}\right)+\ldots \ldots \ldots \\
& \ldots \ldots .+\frac{\left(T-T_{0}\right)\left(T-T_{1}\right) \ldots \ldots \ldots \ldots . .\left(T-T_{n-1}\right)}{\left(T_{n}-T_{0}\right)\left(T_{n}-T_{1}\right) \ldots \ldots . . . .\left(T_{n}-T_{n-1}\right)} f\left(T_{n}\right)+\frac{\left(T-T_{0}\right)\left(T-T_{1}\right) \ldots \ldots \ldots \ldots . .\left(T-T_{n}\right)}{(n+1)!} f^{(n+1)}(\xi)
\end{aligned}
$$

Where $T_{0}<\xi<T_{n}$

This is mathematical expression for estimation of error, if the tabulated values of the function are not equidistant.

## 3 FORMULAS FOR OBTAINING INTERMEDIATE VALUES OF V WITH CONCENTRATION OF SUBSTRATE

Let $V=f(S)$ be a function defined by $n$ points $\left(S_{0}, V_{0}\right),\left(S_{1}, V_{1}\right) \ldots \ldots \ldots\left(S_{n}, V_{n}\right)$. When $S_{1}, S_{2}, S_{3} \ldots \ldots \ldots \ldots S_{n}$ are equally spaced with interval $h$. Where $V$ is the rate of enzymatic reaction and $S$ is the concentration of substrate. And other factors are be constant [1] [2].

### 3.1 If THE POINT Lles in the UPPER half

In this condition we used following formula [1]:
$\mathrm{V}(\mathrm{S})=\mathrm{V}_{0}+\Delta \mathrm{V}_{0}(\mathrm{w})+\frac{\Delta^{2} \mathrm{~V}_{0}}{2!}(\mathrm{w})[(\mathrm{w}-1)] \ldots .+\frac{\Delta^{\mathrm{n}} \mathrm{V}_{0}}{\mathrm{n}!}[(\mathrm{w})\{(\mathrm{w}-1)\} \ldots \ldots .\{(\mathrm{w}-\mathrm{n}\}]$
[Where $\Delta$ is forward difference operator and $\frac{S-S_{0}}{h}=w$ ]

### 3.1.1 ESTIMATION OF ERROR

Let $V=f(S)$ be a function defined by $(n+1)$ points $\left(S_{0}, V_{0}\right),\left(S_{1}, V_{1}\right) \ldots \ldots \ldots .\left(S_{n}, V_{n}\right)$. When $S_{1}, S_{2}, S_{3} \ldots \ldots \ldots . . S_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(S)$ be approximated by a polynomial $P_{n}(S)$ of degree not exceeding a such that

$$
\begin{equation*}
P_{n}\left(S_{i}\right)=V_{i} \quad[\text { Where } i=1,2,3 \ldots \ldots \ldots . n] \tag{25}
\end{equation*}
$$

Since the expression $f(S)-P_{n}(S)$ vanishes for $S_{1}, S_{2}, S_{3} \ldots \ldots \ldots . . . S_{n}$,
We put $f(S)-P_{n}(S)=K \varphi(S)$
Where $\varphi(S)=\left(S-S_{0}\right)\left(S-S_{1}\right)$. $\qquad$ .$\left(S-S_{n}\right)$

And $K$ is to be determined in such a way that equation (26) holds for any intermediate values of $S$, say $S-S^{\prime}$ $\left[\right.$ where $\left.S_{0} \leq S^{\prime} \leq S_{n}\right]$.

Therefore from equation (26)

$$
\begin{equation*}
K=\frac{f\left(S^{\prime}\right)-P\left(S^{\prime}\right)}{\varphi\left(S^{\prime}\right)} \tag{28}
\end{equation*}
$$

Now we construct a function $f(S)$ such that

$$
f\left(S_{0}\right)=f\left(S_{1}\right)-P_{n}(S)-K \varphi(S)
$$

Where $K$ is given by equation (27).
It is clear that:

$$
\begin{equation*}
f\left(S_{0}\right)=f\left(S_{1}\right)=f\left(S_{2}\right)=f\left(S_{3}\right)=\ldots \ldots \ldots \ldots . . . . \tag{29}
\end{equation*}
$$

Let $f(S)$ vanishes $(n+2)$ times in the interval $S_{0} \leq S \leq S_{n}$; consequently, by the repeated application of Rolle's Theorem [15] [16], $f^{\prime}(S)$ must vanish $(n+1)$ times, $f^{\prime \prime}(S)$ must vanish $n$ times etc in the interval $S_{0} \leq S \leq S_{n}$.

Particularly, $f^{(n+1)}(S)$ must vanish once in the interval $S_{0} \leq S \leq S_{n}$. Let this point be $S=Q, S_{0} \leq S \leq S_{n}$.
Now differentiating equation (29) $(n+1)$ times with respect to $S$ and putting $S=Q$, we got:

$$
\begin{align*}
& f^{(n+1)}(Q)-K(n+1)!=0 \\
& \text { Or } \quad K=\frac{f^{(n+1)}(Q)}{(n+1)!} \tag{30}
\end{align*}
$$

Putting this value of $K$ in equation (28), we got:

$$
\begin{gathered}
\frac{f^{(n+1)}(Q)}{(n+1)!}=\frac{f\left(S^{\prime}\right)-P_{n}\left(S^{\prime}\right)}{\varphi\left(S^{\prime}\right)} \\
\text { Or } \quad f\left(S^{\prime}\right)-P_{n}\left(S^{\prime}\right)=\frac{f^{(n+1)}(Q)}{(n+1)!} \varphi\left(S^{\prime}\right), \quad S_{0}<S<S_{n}
\end{gathered}
$$

Since $S^{\prime}$ is arbitrary therefore on dropping the prime on $S^{\prime}$ we got:
$f(S)-P_{n}(S)=\frac{f^{(n+1)}(Q)}{(n+1)!} \varphi(S), \quad S_{0}<S<S_{n}$
Now we use Taylor's theorem [17] [18]:
$f(S+h)=f(Q)+h f^{\prime}(Q)+\frac{h^{2}}{2!} f^{\prime \prime}(Q)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(Q)+\ldots .$.
Neglecting the terms containing second and higher powers of $h$ in equation (32), we got:

$$
f(Q+h)=f(Q)+h f^{\prime}(Q)
$$

Or

$$
\begin{equation*}
f^{\prime}(Q)=\frac{f(Q+h)-f(Q)}{h} \tag{33}
\end{equation*}
$$

Or

$$
\begin{aligned}
& f^{\prime}(Q)=\frac{1}{h} \Delta f(Q) \quad[\therefore \Delta f(S+h) f(S)] \\
& D f(Q)=\frac{1}{h} \Delta f(Q) \quad\left[\therefore D=\frac{d}{d Q}\right] \\
& D=\frac{1}{h} \Delta \quad \quad \text { Because } f(Q) \text { is arbitrary] } \\
& \therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{aligned}
$$

From equation (33), we got:

$$
f^{(n+1)}(Q)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Q)
$$

Putting the values of $f^{(n+1)}(Q)$ in equation (31), we got

$$
\begin{equation*}
f(S)-P_{n}(S)=\left[\frac{\varphi(S)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Q)\right] \tag{34}
\end{equation*}
$$

$f(S)-P_{n}(S)=\left[\frac{\left(S-S_{0}\right)\left(S-S_{1}\right)\left(S-S_{2}\right) \ldots \ldots \ldots \ldots \ldots \ldots . .\left(S-S_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Q)\right]$
If $\frac{S-S_{0}}{h}=r$
Then

$$
\begin{aligned}
& S-S_{0}=h r \\
& S-S_{1}=S-\left(S_{0}+h\right)=\left(S-S_{0}\right)-h=(h r-h)=h(r-1)
\end{aligned}
$$

Similarly $S-S_{2}=h(r-2)$
$:$
$:$
$:$
Similarly $S-S_{n}=h(r-n)$
Putting these values in equation (34), we got:

$$
\begin{aligned}
& f(S)-P_{n}(S)=\left[\frac{(h r)\{h(r-1)\}\{h(r-2)\}\{h(r-3)\} \ldots \ldots \ldots \ldots \ldots .\{(r-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(Q)\right] \\
& f(S)-P_{n}(S)=\left[\frac{r(r-1)(r-2)(r-3) \ldots \ldots \ldots . .(r-n)}{(n+1)!}\right]\left[\Delta^{(n+1)} f(Q)\right]
\end{aligned}
$$

This is mathematical expression for estimation of error, if the point lies in the upper half.

### 3.2 If the point les in the lower half

In this condition we used following formula [1]:

$$
\mathrm{V}(\mathrm{~S})=\mathrm{V}_{\mathrm{n}}+\nabla \mathrm{V}_{\mathrm{n}}(\mathrm{~J})+\frac{\nabla^{2} \mathrm{~V}_{\mathrm{n}}}{2!}[\{\mathrm{J}(\mathrm{~J}+1)\}]+\ldots . .+\frac{\nabla^{\mathrm{n}} \mathrm{~V}_{\mathrm{n}}}{\mathrm{n}!}[(\mathrm{J})\{(\mathrm{J}+1)\} . .\{\mathrm{J}+(\mathrm{n}-1)\}]
$$

[Where $\nabla$ is backward difference operator and $\frac{S-S_{n}}{h}=J$ ]

### 3.2.1 Estimation of ERROR

Let $V=f(S)$ be a function defined by $(n+1)$ points $\left(S_{0}, V_{0}\right),\left(S_{1}, V_{1}\right) \ldots \ldots \ldots . .\left(S_{n}, V_{n}\right)$. When $S_{1}, S_{2}, S_{3} \ldots \quad S_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(S)$ be approximated by a polynomial $P_{n}(S)$ of degree not exceeding a such that

$$
\begin{equation*}
P_{n}\left(S_{i}\right)=V_{i} \quad[\text { Where } i=1,2,3 \ldots \ldots . . . . n] \tag{35}
\end{equation*}
$$

Since the expression $f(S)-P_{n}(S)$ vanishes for $S_{1}, S_{2}, S_{3} \ldots \quad S_{n}$,
We put $f(S)-P_{n}(S)=K \varphi(S)$

Where $\varphi(S)=\left(S-S_{0}\right)\left(S-S_{1}\right)$ $\qquad$ $\left(S-S_{n}\right)$

And $K$ is to be determined in such a way that equation (36) holds for any intermediate values of $S$, say $S-S^{\prime}$ $\left[\right.$ where $S_{0} \leq S^{\prime} \leq S_{n}$ ].

Therefore from (2)

$$
\begin{equation*}
K=\frac{f\left(S^{\prime}\right)-P\left(S^{\prime}\right)}{\varphi_{1}\left(S^{\prime}\right)} \tag{38}
\end{equation*}
$$

Now we construct a function $f(S)$ such that
$f\left(S_{0}\right)=f\left(S_{1}\right)-P_{n}(S)-K \varphi_{1}(S)$
Where $K$ is given by equation (37).
It is clear that

$$
\begin{equation*}
f\left(S_{0}\right)=f\left(S_{1}\right)=f\left(S_{2}\right)=f\left(S_{3}\right)=\ldots \ldots \ldots \ldots f\left(S_{n}\right)=f\left(S^{\prime}\right)=0 \tag{39}
\end{equation*}
$$

Let $f(S)$ vanishes $(n+2)$ times in the interval $S_{0} \leq S \leq S_{n}$; consequently, by the repeated application of Rolle's Theorem [15][16], $f^{\prime}(S)$ must vanish $(n+1)$ times, $f^{\prime \prime}(S)$ must vanish $n$ times etc in the interval $S_{0} \leq S \leq S_{n}$.

Particularly, $f^{(n+1)}(S)$ must vanish once in the interval $S_{0} \leq S \leq S_{n}$. Let this point be $S=R, S_{0} \leq S \leq S_{n}$.

Now differentiating equation (39) ( $n+1$ ) times with respect to $S$ and putting $S=R$, we got:

$$
\begin{array}{r}
f^{(n+1)}(R)-K(n+1)!=0 \\
\text { Or } \quad K=\frac{f^{(n+1)}(R)}{(n+1)!}
\end{array}
$$

Putting this value of $K$ in equation (38), we got:

$$
\frac{f^{(n+1)}(R)}{(n+1)!}=\frac{f\left(S^{\prime}\right)-P_{n}\left(S^{\prime}\right)}{\varphi_{1}\left(S^{\prime}\right)}
$$

Or

$$
f\left(S^{\prime}\right)-P_{n}\left(S^{\prime}\right)=\frac{f^{(n+1)}(R)}{(n+1)!} \varphi_{1}\left(S^{\prime}\right), \quad S_{0}<S<S_{n}
$$

Since $S^{\prime}$ is arbitrary therefore on dropping the prime on $S^{\prime}$ we got:

$$
\begin{equation*}
f(S)-P_{n}(S)=\frac{f^{(n+1)}(R)}{(n+1)!} \varphi_{1}(S), \quad S_{0}<S<S_{n} \tag{41}
\end{equation*}
$$

Now we use Taylor's theorem [17][18]:
$f(S+h)=f(R)+h f^{\prime}(R)+\frac{h^{2}}{2!} f^{\prime \prime}(R)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(R)+\ldots .$.
Neglecting the terms containing second and higher powers of $h$ in equation (42), we got:

$$
f(R+h)=f(R)+h f^{\prime}(R)
$$

Or

$$
\begin{equation*}
f^{\prime}(R)=\frac{f(R+h)-f(R)}{h} \tag{43}
\end{equation*}
$$

Or

$$
\begin{aligned}
& f^{\prime}(R)=\frac{1}{h} \Delta f(R) \quad[\therefore \Delta f(S+h) f(S)] \\
& D f(R)=\frac{1}{h} \Delta f(R) \quad\left[\therefore D=\frac{d}{d R}\right] \\
& D=\frac{1}{h} \Delta \quad \quad \text { Because } f(R) \text { is arbitrary] } \\
& \therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{aligned}
$$

From equation (43), we got:

$$
f^{(n+1)}(R)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)
$$

Putting the values of $f^{(n+1)}(R)$ in equation (41), we got

$$
f(S)-P_{n}(S)=\left[\frac{\varphi_{1}(S)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right]
$$

$f(S)-P_{n}(S)=\left[\frac{\left(S-S_{0}\right)\left(S-S_{1}\right)\left(S-S_{2}\right) \ldots \ldots \ldots \ldots \ldots .\left(S-S_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right]$
If $\frac{S-S_{n}}{h}=J$
Then

$$
\begin{aligned}
& S-S_{n}=h J \\
& S-S_{n-1}=S-\left(S_{n}-h\right)=\left(S-S_{n}\right)+h=(h J+h)=h(J+1)
\end{aligned}
$$

Similarly $S-S_{n-2}=h(J+2)$
:
:
:
Similarly $S-S_{0}=h(J+n)$
Putting these values in equation (44), we got:

$$
\begin{aligned}
& f(S)-P_{n}(S)=\left[\frac{(h J)\{h(J-1)\}\{h(J-2)\}\{h(J-3)\} \ldots \ldots \ldots \ldots \ldots\{(J-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right] \\
& f(S)-P_{n}(S)=\left[\frac{J(J-1)(J-2)(J-3) \ldots \ldots \ldots(J-n)}{(n+1)!}\right]\left[\Delta^{(n+1)} f(R)\right]
\end{aligned}
$$

This is mathematical expression for estimation of error, if the point lies in the lower half.

### 3.3 If Intervals are not be equally spaced

In this condition we used following formula [1]:
$\mathrm{V}(\mathrm{S})=\mathrm{V}_{1}+\Delta_{\mathrm{d}} \mathrm{V}_{1}\left(\mathrm{~S}-S_{1}\right)+\Delta_{\mathrm{d}}^{2} \mathrm{~V}_{1}\left(\mathrm{~S}-S_{1}\right)\left(\mathrm{S}-S_{2}\right)+\ldots .+\Delta_{\mathrm{d}}^{\mathrm{n}} \mathrm{V}_{1}\left[\left(\mathrm{~S}-\mathrm{S}_{1}\right)\left(\mathrm{S}-S_{2}\right) \ldots\left(\mathrm{S}-S_{\mathrm{n}}\right)\right]$
[Where $\Delta_{d}$ is divide difference operator]

### 3.3.1 ESTIMATION OF ERROR

Let $f(S)$ be a real-valued function define $n$ interval and $(n+1)$ times differentiable on $(a, b)$. If $P_{n}(S)$ is the polynomial. Which interpolates $f(S)$ at the $(n+1)$ distinct points $S_{0}, S_{1} \ldots . . S_{n} \in(a, b)$, then for all $\bar{T} \in[a, b]$, there exists $\xi=\xi(\bar{S}) \in(a, b)$

$$
\begin{align*}
e_{n}(\bar{S}) & =f(\bar{S})-P_{n}(\bar{S}) \\
& =\frac{f^{(n+1)}(\xi)}{(n+1)} \prod_{j=0}^{n}\left(\bar{S}-S_{j}\right) \tag{45}
\end{align*}
$$

This is mathematical expression for estimation of error, if intervals are not be equally spaced.

### 3.4 When the tabulated values of the function are not equidistant

In this condition we used following formula [2]:

$$
V(S)=\sum_{i=1}^{n} V_{i} \prod_{\substack{j=1 \\ j \neq i}}^{n} \frac{\left(S-S_{i}\right)}{\left(S_{i}-S_{j}\right)}
$$

### 3.4.1 Estimation of ERROR

Since the approximating polynomial $f(S)$ given by Lagrangian formula has the same values $f\left(S_{0}\right) f\left(S_{1}\right) f\left(S_{2}\right) f\left(S_{3}\right)$ $f\left(S_{4}\right) \ldots \ldots . . . . . f\left(S_{n}\right)$ as does $V=f(S)$ for the arguments $S_{0}, S_{1}, S_{2}, S_{3}, S_{4}$ $\qquad$ $S_{n}$ the error term must have zeros at these $(n+1)$ points.

Therefore $\left(S-S_{0}\right)\left(S-S_{1}\right)\left(S-S_{2}\right)\left(S-S_{3}\right)$ $\qquad$ ( $S-S_{n}$ ) must be factors of the error and we can write:
$F(S)=f(S)+\frac{\left(S-S_{0}\right)\left(S-S_{1}\right)\left(S-S_{2}\right)\left(S-S_{3}\right) \ldots \ldots \ldots \ldots \ldots \ldots\left(S-S_{n}\right)}{(n+1)!} K(S)$
Let $S$ to be fixed in value and consider the function

$$
\begin{equation*}
W(x)=F(x)-f(x) \frac{\left(x-S_{0}\right)\left(x-S_{1}\right)\left(x-S_{2}\right)\left(x-S_{3}\right) \ldots \ldots \ldots \ldots \ldots\left(x-S_{n}\right)}{(n+1)!} K(S) \tag{47}
\end{equation*}
$$

Then $W(x)$ has zero $x=S_{0}, S_{1}, S_{2}, S_{3 \ldots \ldots \ldots \ldots . . .} S_{n}$ and $S$.
Since the $(n+1)^{\text {th }}$ derivative of the $n^{\text {th }}$ degree polynomial $f(S)$ is zero.

$$
\begin{equation*}
W^{(n+1)}(x)=F^{(n+1)}(x)-K(S) \tag{48}
\end{equation*}
$$

As a consequence of Rolle's Theorem [15] [16], the $(n+1)^{\text {th }}$ derivative of $W(x)$ has at least one real zero $x=\xi$ in the range $S_{0}<\xi<S_{n}$

Therefore substituting $x=\xi$ in equation (48)

Or

$$
W^{(n+1)}(\xi)=F^{(n+1)}(\xi)-K(S)
$$

$$
\begin{aligned}
K(S) & =F^{(n+1)}(\xi)-W^{(n+1)}(\xi) \\
& =F^{(n+1)}(\xi)
\end{aligned}
$$

Using this expression for $K(S)$ and writing out $f(S)$

$$
\begin{aligned}
f(S)= & \frac{\left(S-S_{1}\right)\left(S-S_{2}\right) \ldots \ldots \ldots \ldots .\left(S-S_{n}\right)}{\left(S_{0}-S_{1}\right)\left(S_{0}-S_{2}\right) \ldots \ldots \ldots \ldots .\left(S_{0}-S_{n}\right)} f\left(S_{0}\right)+\frac{\left(S-S_{0}\right)\left(S-S_{2}\right) \ldots \ldots \ldots \ldots .\left(S-S_{n}\right)}{\left(S_{1}-S_{0}\right)\left(S_{1}-S_{2}\right) \ldots \ldots \ldots \ldots\left(S_{1}-S_{n}\right)} f\left(S_{1}\right)+\ldots \ldots . . \\
& \ldots \ldots+\frac{\left(S-S_{0}\right)\left(S-S_{1}\right) \ldots \ldots \ldots \ldots\left(S-S_{n-1}\right)}{\left(S_{n}-S_{0}\right)\left(S_{n}-S_{1}\right) \ldots \ldots \ldots \ldots .\left(S_{n}-S_{n-1}\right)} f\left(S_{n}\right)+\frac{\left(S-S_{0}\right)\left(S-S_{1}\right) \ldots \ldots \ldots \ldots .\left(S-S_{n}\right)}{(n+1)!} f^{(n+1)}(\xi)
\end{aligned}
$$

Where $S_{0}<\xi<S_{n}$
This is mathematical expression for estimation of error, if the tabulated values of the function are not equidistant.

## 4 FORMULAS FOR OBTAINING INTERMEDIATE VALUES OF V WITH CONCENTRATION OF ENZYME

Let $V=f(E)$ be a function defined by $n$ points $\left(E_{0}, V_{0}\right),\left(E_{1}, V_{1}\right)$. $\qquad$ . $\left(E_{n}, V_{n}\right)$. When $E_{1}, E_{2}, E_{3}$ $\qquad$ $E_{n}$ are equally spaced with interval $h$. Where $\boldsymbol{V}$ is the rate of enzymatic reaction and $E$ is the concentration of enzyme. And other factors are be constant [1] [2].

### 4.1 If THE POINT LIES in the UPPER half

In this condition we used following formula [1]:
$\mathrm{V}(\mathrm{E})=\mathrm{V}_{0}+\Delta \mathrm{V}_{0}(\mathrm{X})+\frac{\Delta^{2} \mathrm{~V}_{0}}{2!}(\mathrm{X})[(\mathrm{X}-1)] \ldots . .+\frac{\Delta^{\mathrm{n}} \mathrm{V}_{0}}{\mathrm{n}!}[(\mathrm{X})\{(\mathrm{X}-1)\} \ldots \ldots . .\{(\mathrm{X}-\mathrm{n}\}]$
[Where $\Delta$ is forward difference operator and $\frac{E-E_{0}}{h}=X$ ]

### 4.1.1 ESTIMATION OF ERROR

Let $V=f(E)$ be a function defined by $(n+1)$ points $\left(E_{0}, V_{0}\right),\left(E_{1}, V_{1}\right)$. $\qquad$ . $\left(E_{n}, V_{n}\right)$. When $E_{1}, E_{2}, E_{3} \ldots \ldots \ldots \ldots . E_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(E)$ be approximated by a polynomial $P_{n}(E)$ of degree not exceeding a such that
$P_{n}\left(E_{i}\right)=V_{i}$
[Where $i=1,2,3$ $\qquad$ . $n$ ]

Since the expression $f(E)-P_{n}(E)$ vanishes for $E_{1}, E_{2}, E_{3} \ldots \ldots \ldots . . . E_{n}$,
We put $f(E)-P_{n}(E)=K \varphi(E)$
Where $\varphi(E)=\left(E-E_{0}\right)\left(E-E_{1}\right)$. $\qquad$ .$\left(E-E_{n}\right)$

And $K$ is to be determined in such a way that equation (50) holds for any intermediate values of $E$, say $E-E^{\prime}$ $\left[\right.$ where $E_{0} \leq E^{\prime} \leq E_{n}$ ].

Therefore from (50)

$$
\begin{equation*}
K=\frac{f\left(E^{\prime}\right)-P\left(E^{\prime}\right)}{\varphi\left(E^{\prime}\right)} \tag{52}
\end{equation*}
$$

Now we construct a function $f(E)$ such that

$$
f\left(E_{0}\right)=f\left(E_{1}\right)-P_{n}(E)-K \varphi(E)
$$

Where $K$ is given by equation (52).
It is clear that: $\quad f\left(E_{0}\right)=f\left(E_{1}\right)=f\left(E_{2}\right)=f\left(E_{3}\right)=\ldots \ldots \ldots \ldots . . . f\left(E_{n}\right)=f\left(E^{\prime}\right)=0$

Let $f(E)$ vanishes $(n+2)$ times in the interval $E_{0} \leq E \leq E_{n}$; consequently, by the repeated application of Rolle's Theorem [15] [16], $f^{\prime}(E)$ must vanish $(n+1)$ times, $f^{\prime \prime}(E)$ must vanish $n$ times etc in the interval $E_{0} \leq E \leq E_{n}$.

Particularly, $f^{(n+1)}(E)$ must vanish once in the interval $E_{0} \leq E \leq E_{n}$. Let this point be $E=R, E_{0} \leq E \leq E_{n}$.
Now differentiating equation (53) $(n+1)$ times with respect to $E$ and putting $E=R$, we got:

$$
\begin{gather*}
f^{(n+1)}(R)-K(n+1)!=0 \\
K=\frac{f^{(n+1)}(R)}{(n+1)!} \tag{54}
\end{gather*}
$$

Or

Putting this value of $K$ in equation (52), we got:

Or

$$
\begin{aligned}
\frac{f^{(n+1)}(R)}{(n+1)!} & =\frac{f\left(E^{\prime}\right)-P_{n}\left(E^{\prime}\right)}{\varphi\left(E^{\prime}\right)} \\
f\left(E^{\prime}\right)-P_{n}\left(E^{\prime}\right) & =\frac{f^{(n+1)}(R)}{(n+1)!} \varphi\left(E^{\prime}\right), \quad E_{0}<E<E_{n}
\end{aligned}
$$

Since $E^{\prime}$ is arbitrary therefore on dropping the prime on $E^{\prime}$ we got:

$$
\begin{equation*}
f(E)-P_{n}(E)=\frac{f^{(n+1)}(R)}{(n+1)!} \varphi(E), \quad E_{0}<E<E_{n} \tag{55}
\end{equation*}
$$

Now we use Taylor's theorem [17] [18]:
$f(E+h)=f(R)+h f^{\prime}(R)+\frac{h^{2}}{2!} f^{\prime \prime}(R)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(R)+\ldots .$.
Neglecting the terms containing second and higher powers of $h$ in equation (56), we got:

Or

$$
\begin{align*}
& f(R+h)=f(R)+h f^{\prime}(R) \\
& f^{\prime}(R)=\frac{f(R+h)-f(R)}{h}  \tag{57}\\
& f^{\prime}(R)=\frac{1}{h} \Delta f(R) \quad[\therefore \Delta f(E+h) f(E)] \\
& D f(R)=\frac{1}{h} \Delta f(R) \quad\left[\therefore D=\frac{d}{d R}\right] \\
& D=\frac{1}{h} \Delta \quad \quad \text { Because } f(R) \text { is arbitrary] } \\
& \therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{align*}
$$

Or

From equation (57), we got:

$$
f^{(n+1)}(R)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)
$$

Putting the values of $f^{(n+1)}(R)$ in equation (57), we got

$$
f(E)-P_{n}(E)=\left[\frac{\varphi(E)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right]
$$

$f(E)-P_{n}(E)=\left[\frac{\left(E-E_{0}\right)\left(E-E_{1}\right)\left(E-E_{2}\right) \ldots \ldots \ldots \ldots \ldots . . . . .\left(E-E_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right]$
If $\frac{E-E_{0}}{h}=x$
Then

$$
\begin{aligned}
& E-E_{0}=h X \\
& E-E_{1}=E-\left(E_{0}+E\right)=\left(E-E_{0}\right)-h=(h X-h)=h(X-1)
\end{aligned}
$$

Similarly $E-E_{2}=h(X-2)$

```
:
```

:
:
Similarly $E-E_{n}=h(X-n)$
Putting these values in equation (58), we got:

$$
\begin{aligned}
& f(E)-P_{n}(E)=\left[\frac{(h X)\{h(X-1)\}\{h(X-2)\}\{h(X-3)\} \ldots \ldots \ldots \ldots \ldots .\{(X-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right] \\
& f(E)-P_{n}(E)=\left[\frac{X(X-1)(e-2)(X-3) \ldots \ldots \ldots .(X-n)}{(n+1)!}\right]\left[\Delta^{(n+1)} f(R)\right]
\end{aligned}
$$

This is mathematical expression for estimation of error, if the point lies in the upper half.

### 4.2 If the point les in the lower half

In this condition we used following formula [1]:
$V(E)=V_{n}+\nabla V_{n}(e)+\frac{\nabla^{2} V_{n}}{2!}[\{e(e+1)\}]+\ldots . .+\frac{\nabla^{n} V_{n}}{n!}[(e)\{(e+1)\} . .\{e+(n-1)\}]$
[Where $\nabla$ is backward difference operator and $\frac{E-E_{n}}{h}=e$ ]

### 4.2.1 Estimation of ERROR

Let $V=f(E)$ be a function defined by $(n+1)$ points $\left(E_{0}, V_{0}\right),\left(E_{1}, V_{1}\right)$. $\qquad$ ..$\left(E_{n}, V_{n}\right)$. When $E_{1}, E_{2}, E_{3} \ldots \ldots \ldots \ldots . . . E_{n}$ are equally spaced with interval $h$ and this function is continuous and differentiable $(n+1)$ times.

Let $V=f(E)$ be approximated by a polynomial $P_{n}(E)$ of degree not exceeding a such that
$P_{n}\left(E_{i}\right)=V_{i} \quad[$ Where $i=1,2,3 \ldots \ldots \ldots . n]$
Since the expression $f(E)-P_{n}(E)$ vanishes for $E_{1}, E_{2}, E_{3} \ldots \ldots \ldots . . . E_{n}$,
We put $f(E)-P_{n}(E)=K \varphi(E)$
Where $\varphi(E)=\left(E-E_{0}\right)\left(E-E_{1}\right)$. $\qquad$ .$\left(E-E_{n}\right)$

And $K$ is to be determined in such a way that equation (60) holds for any intermediate values of $E$, say $E-E^{\prime}$ [where $E_{0} \leq E^{\prime} \leq E_{n}$ ].

Therefore from (60)

$$
\begin{equation*}
K=\frac{f\left(E^{\prime}\right)-P\left(E^{\prime}\right)}{\varphi_{1}\left(E^{\prime}\right)} \tag{62}
\end{equation*}
$$

Now we construct a function $f(E)$ such that

$$
f\left(E_{0}\right)=f\left(E_{1}\right)-P_{n}(E)-K \varphi_{1}(E)
$$

Where $K$ is given by equation (62).
It is clear that

$$
\begin{equation*}
f\left(E_{0}\right)=f\left(E_{1}\right)=f\left(E_{2}\right)=f\left(E_{3}\right)=\ldots \ldots \ldots \ldots f\left(E_{n}\right)=f\left(E^{\prime}\right)=0 \tag{63}
\end{equation*}
$$

Let $f(E)$ vanishes $(n+2)$ times in the interval $E_{0} \leq E \leq E_{n}$; consequently, by the repeated application of Rolle's Theorem [15] [16], $f^{\prime}(E)$ must vanish $(n+1)$ times, $f^{\prime \prime}(E)$ must vanish $n$ times etc in the interval $E_{0} \leq E \leq E_{n}$.

Particularly, $f^{(n+1)}(E)$ must vanish once in the interval $E_{0} \leq E \leq E_{n}$. Let this point be $E=R, E_{0} \leq E \leq E_{n}$.
Now differentiating equation (5) $(n+1)$ times with respect to $E$ and putting $E=R$, , we got:

$$
\begin{align*}
& \text { Or } \begin{aligned}
& f^{(n+1)}(R)-K(n+1)!=0 \\
& K=\frac{f^{(n+1)}(R)}{(n+1)!}
\end{aligned}, ~
\end{align*}
$$

Putting this value of $K$ in equation (62), we got:

Or

$$
\begin{aligned}
\frac{f^{(n+1)}(R)}{(n+1)!} & =\frac{f\left(E^{\prime}\right)-P_{n}\left(E^{\prime}\right)}{\varphi_{1}\left(E^{\prime}\right)} \\
f\left(E^{\prime}\right)-P_{n}\left(E^{\prime}\right)= & \frac{f^{(n+1)}(R)}{(n+1)!} \varphi_{1}\left(E^{\prime}\right), \quad E_{0}<E<E_{n}
\end{aligned}
$$

Since $E^{\prime}$ is arbitrary therefore on dropping the prime on $E^{\prime}$ we got:

$$
\begin{equation*}
f(E)-P_{n}(E)=\frac{f^{(n+1)}(R)}{(n+1)!} \varphi_{1}(E), \quad E_{0}<E<E_{n} \tag{65}
\end{equation*}
$$

Now we use Taylor's theorem [17] [18]:
$f(E+h)=f(R)+h f^{\prime}(R)+\frac{h^{2}}{2!} f^{\prime \prime}(R)+\ldots \ldots \ldots+\frac{h^{n}}{n!} f^{n}(R)+\ldots$.
Neglecting the terms containing second and higher powers of $h$ in equation (66), we got:

$$
f(R+h)=f(R)+h f^{\prime}(R)
$$

Or

$$
\begin{equation*}
f^{\prime}(R)=\frac{f(R+h)-f(R)}{h} \tag{67}
\end{equation*}
$$

Or

$$
\begin{array}{cr}
f^{\prime}(R)=\frac{1}{h} \Delta f(R) & {[\therefore \Delta f(E+h) f(E)]} \\
D f(R)=\frac{1}{h} \Delta f(R) & {\left[\therefore D=\frac{d}{d R}\right]}
\end{array}
$$

$$
\begin{gathered}
D=\frac{1}{h} \Delta \quad[\text { Because } f(R) \text { is arbitrary] } \\
\therefore D^{n+1}=\frac{1}{h^{n+1}} \Delta^{n+1}
\end{gathered}
$$

From equation (67), we got:

$$
f^{(n+1)}(R)=\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)
$$

Putting the values of $f^{(n+1)}(R)$ in equation (65), we got

$$
\begin{align*}
& f(E)-P_{n}(E)=\left[\frac{\varphi_{1}(E)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right] \\
& f(E)-P_{n}(E)=\left[\frac{\left(E-E_{0}\right)\left(E-E_{1}\right)\left(E-E_{2}\right) \ldots \ldots \ldots \ldots \ldots . .\left(E-E_{0}\right)}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right] \tag{68}
\end{align*}
$$

If $\frac{E-E_{n}}{h}=e$
Then

$$
\begin{aligned}
& E-E_{n}=h e \\
& E-E_{n-1}=E-\left(E_{n}-h\right)=\left(E-E_{n}\right)+h=(h e+h)=h(e+1)
\end{aligned}
$$

Similarly $E-E_{n-2}=h(e+2)$
:
:

Similarly $E-E_{0}=h(e+n)$
Putting these values in equation (68), we got:

$$
\begin{aligned}
& f(E)-P_{n}(E)=\left[\frac{(h e)\{h(e-1)\}\{h(e-2)\}\{h(e-3)\} \ldots \ldots \ldots \ldots . .\{(e-n)\}}{(n+1)!}\right]\left[\frac{1}{h^{(n+1)}} \Delta^{(n+1)} f(R)\right] \\
& f(E)-P_{n}(E)=\left[\frac{e(e-1)(e-2)(e-3) \ldots \ldots \ldots .(e-n)}{(n+1)!}\right]\left[\Delta^{(n+1)} f(R)\right]
\end{aligned}
$$

This is mathematical expression for estimation of error, if the point lies in the lower half.

### 4.3 If Intervals are not be equally spaced

In this condition we used following formula [1]:

$$
\mathrm{V}(\mathrm{E})=\mathrm{V}_{1}+\Delta_{\mathrm{d}} \mathrm{~V}_{1}\left(\mathrm{E}-E_{1}\right)+\Delta_{\mathrm{d}}^{2} \mathrm{~V}_{1}\left(\mathrm{E}-E_{1}\right)\left(\mathrm{E}-E_{2}\right)+\ldots . .+\Delta_{\mathrm{d}}^{\mathrm{n}} \mathrm{~V}_{1}\left[\left(\mathrm{E}-E_{1}\right)\left(\mathrm{E}-E_{2}\right) \ldots\left(\mathrm{E}-E_{\mathrm{n}}\right)\right]
$$

[Where $\Delta_{d}$ is divide difference operator]

### 4.3.1 ESTIMATION OF ERROR

Let $f(E)$ be a real-valued function define $n$ interval and $(n+1)$ times differentiable on $(a, b)$. If $P_{n}(E)$ is the polynomial. Which interpolates $f(E)$ at the $(n+1)$ distinct points $E_{0,} E_{1 \ldots \ldots}, E_{n} \in(a, b)$, then for all $\bar{T} \in[a, b]$, there exists $\xi=\xi(\bar{E}) \in(a, b)$

$$
\begin{align*}
e_{n}(\bar{E}) & =f(\bar{E})-P_{n}(\bar{E}) \\
& =\frac{f^{(n+1)}(\xi)}{(n+1)} \prod_{j=0}^{n}\left(\bar{E}-E_{j}\right) \tag{69}
\end{align*}
$$

This is mathematical expression for estimation of error, if intervals are not be equally spaced.

### 4.4 When the tabulated values of the function are not equidistant

In this condition we used following formula [2]:

$$
\mathrm{V}(\mathrm{E})=\sum_{i=1}^{n} \mathrm{~V}_{i} \prod_{\substack{j=1 \\ j \neq i}}^{n} \frac{\left(\mathrm{E}-\mathrm{E}_{j}\right)}{\left(\mathrm{E}_{i}-\mathrm{E}_{j}\right)}
$$

### 4.4.1 Estimation of ERROR

Since the approximating polynomial $f(E)$ given by Lagrangian formula has the same values $f\left(E_{0}\right) f\left(E_{1}\right) f\left(E_{2}\right)$ $f\left(E_{3}\right) f\left(E_{4}\right) \ldots \ldots . . . . . . f\left(E_{n}\right)$ as does $V=f(E)$ for the arguments $E_{0}, E_{1}, E_{2}, E_{3}, E_{4} \ldots \ldots . . . . . . . . . . . . . ., E_{n}$ the error term must have zeros at these $(n+1)$ points.

Therefore $\left(E-E_{0}\right)\left(E-E_{1}\right)\left(E-E_{2}\right)\left(E-E_{3}\right)$ $\qquad$ ( $E-E_{n}$ ) must be factors of the error and we can write:

$$
\begin{equation*}
F(E)=f(E)+\frac{\left(E-E_{0}\right)\left(E-E_{1}\right)\left(E-E_{2}\right)\left(E-E_{3}\right) \ldots \ldots \ldots \ldots \ldots \ldots\left(E-E_{n}\right)}{(n+1)!} K(E) \tag{70}
\end{equation*}
$$

Let $E$ to be fixed in value and consider the function

$$
\begin{equation*}
W(x)=F(x)-f(x) \frac{\left(x-E_{0}\right)\left(x-E_{1}\right)\left(x-E_{2}\right)\left(x-E_{3}\right) \ldots \ldots \ldots \ldots \ldots .\left(x-E_{n}\right)}{(n+1)!} K(E) \tag{71}
\end{equation*}
$$

Then $W(x)$ has zero $x=E_{0}, E_{1}, E_{2}, E_{3} \ldots \ldots \ldots \ldots . . . E_{n}$ and $E$.
Since the $(n+1)^{\text {th }}$ derivative of the $n^{t h}$ degree polynomial $f(E)$ is zero.

$$
\begin{equation*}
W^{(n+1)}(x)=F^{(n+1)}(x)-K(E) \tag{72}
\end{equation*}
$$

As a consequence of Rolle's Theorem [15] [16] the $(n+1)^{\text {th }}$ derivative of $W(x)$ has at least one real zero $x=\xi$ in the range $E_{0}<\xi<E_{n}$

Therefore substituting $x=\xi$ in equation (73):

Or

$$
W^{(n+1)}(\xi)=F^{(n+1)}(\xi)-K(E)
$$

$$
\begin{aligned}
K(E) & =F^{(n+1)}(\xi)-W^{(n+1)}(\xi) \\
& =F^{(n+1)}(\xi)
\end{aligned}
$$

Using this expression for $K(S)$ and writing out $f(S)$

$$
\begin{aligned}
f(E)= & \frac{\left(E-E_{1}\right)\left(E-E_{2}\right) \ldots \ldots \ldots \ldots . .\left(E-E_{n}\right)}{\left(E_{0}-E_{1}\right)\left(E_{0}-E_{2}\right) \ldots \ldots \ldots \ldots . .\left(E_{0}-E_{n}\right)} f\left(E_{0}\right)+\frac{\left(E-E_{0}\right)\left(E-E_{2}\right) \ldots \ldots \ldots \ldots . .\left(E-E_{n}\right)}{\left(E_{1}-E_{0}\right)\left(E_{1}-E_{2}\right) \ldots \ldots \ldots \ldots \ldots .\left(E_{1}-E_{n}\right)} f\left(E_{1}\right)+\ldots \ldots . . \\
& \ldots \ldots \ldots+\frac{\left(E-E_{0}\right)\left(E-E_{1}\right) \ldots \ldots \ldots \ldots . .\left(E-E_{n-1}\right)}{\left(E_{n}-E_{0}\right)\left(E_{n}-E_{1}\right) \ldots \ldots \ldots \ldots . .\left(E_{n}-E_{n-1}\right)} f\left(E_{n}\right)+\frac{\left(E-E_{0}\right)\left(E-E_{1}\right) \ldots \ldots \ldots . .\left(E-E_{n}\right)}{(n+1)!} f^{(n+1)}(\xi)
\end{aligned} \text { Where } E_{0}<\xi<E_{n}
$$

This is mathematical expression for estimation of error, if the tabulated values of the function are not equidistant.

## 5 CONCLUSION

Derived mathematical expressions are useful to estimation of the errors in the formulas for obtaining intermediate values of the rate of enzymatic reaction. All expressions are worked in $n$ limit which is the optimum limit. When we obtain the intermediate values of the rate of enzymatic reaction then these mathematical expressions are useful to estimate the errors in interpolated values of the rate of enzymatic reaction.
